## WHAT IS DESIGN FOR DISASSEMBLY?

Design for disassembly (DfD) is a strategy to design and build a structure with its end of life in mind. DfD also considers the end of life of products installed in the building and their replacement during the life of the building, including ongoing maintenance and renovations, as well as during the decommissioning of the building. During the design phase, the changes over time of the programming of the building are anticipated and accommodated, as is the deconstruction of the building itself. DfD principles cover all building components including structural elements, finishing products as well as mechanical, electrical, and plumbing systems (MEP).

This concept helps shift the mindset of the construction industry to look at buildings as a store of materials that can be harvested for reuse. The ability to do this could dramatically reduce the amount of waste produced on the regional scale. For example, in Metro Vancouver, the construction and demolition industry produces more than 30% of the total waste to the landfill<sup>1</sup>. Although we are seeing higher and higher volumes of materials go to recycling facilities, recycling still requires immense resources to process the materials. Through recycling streams, materials are typically downcycled, and the products made with these materials are not usually able to be furthered recycled at end of life and ultimately end up in the landfill. With this in mind, we want to create an industry for salvaged goods and opportunities to create a circular system where materials can be integrated into the design of new buildings. We have seen this done already in keystone projects such as the C.K. Choi building and others.

The goals of DfD strategies are to:

1. Simplify the deconstruction process
2. Reduce time and cost for deconstruction
3. Allow for maximum recovery of components and materials <sup>2</sup>

**Design for Disassembly Principles:**

The following table shows the relevance of design for disassembly principles to the participants of a construction project. Designers have the most influence on whether these principles are implemented, but each participant has a role in ensuring that disassembly can occur, and each principle relies on more than one participant to ensure its incorporation and ultimate success.

Design Principles	Owners	Architects	Engineers	General Contractor/ CM	Specialty/ Subcontractors	Fabricators/ Manufacturers	Suppliers
1 Design for prefabrication, preassembly and modular construction		High	High	Medium	High	High	
2 Simplify and standardize connection details		Medium	High	Medium	High	High	Medium
3 Simplify and separate building systems		High	High	Medium	Medium		
4 Consider worker safety during deconstruction & construction		Medium	Medium	High	Medium	Medium	Medium
5 Minimize building components and materials		High	Medium	Medium	Medium	Medium	Medium
6 Select fittings, fasteners, adhesives and sealants that allow for quicker disassembly and facilitate the removal of reusable materials		Medium	High	Medium	High	High	High
7 Design to accommodate deconstruction logistics		High	High	Medium	Medium		
8 Reduce building complexity	Medium	High	Medium		Medium		
9 Design to reusable materials	Medium	High	Medium	Medium	Medium	Medium	Medium
10 Design for flexibility and adaptability	High	High	Medium				

High relevance  
 Medium relevance

## WHAT IS THE PURPOSE OF THIS REPORT?

The purpose of this research is to find resources for designers and architects to be able to implement DfD principles for residential construction in general, highlighting the opportunities to use wood. However, these resources include information that can apply toward all types of construction and building types.

We hope this report contains information that can immediately be incorporated into projects to increase their potential for deconstruction and disassembly. In BC, wood is an important building material, both because it is locally available and for the economic benefit it provides to communities across the province. Wood in construction also has the environmental benefit of sequestering carbon for decades, and with its high potential for reuse, we can extend that sequestration to centuries.

Finally, creating a truly circular building industry would require that salvaged and recycled material use is prioritized in construction. In order to “close the loop”, we have included resources for designing with, and sourcing salvaged material.

## MATERIAL RECOMMENDATIONS

Although Design for Disassembly is not a new strategy, its adoption, by the construction industry and the manufacturers that supply the industry, has been slow. North American construction methods favour speed and low-cost over the recoverability of materials. However, DfD can reduce the cost of maintaining and renovating a building, by using good quality materials and allowing for the easy replacement of components that have a shorter life spans than the building itself. It is in the owners’ and operators’ best interests to incorporate materials that lend themselves to DfD.

Specific product recommendations are challenging considering the current state of the market with DfD resources. However, there are many strategies and methods of design and construction that can provide guidance for design and construction teams.

### ***Material selection:***

- Choose durable materials that are long-lasting, good quality, and can withstand the disassembly process.
- Choose materials with recycling potential if they will not be reused at the end of their life.
- Choose materials that have an end-of-life plan in place:
  - A take back program to return the material to the supplier
  - Cradle to Cradle<sup>3</sup> certification
- Source salvaged goods to be used in the structural and finishing materials. A material that has already demonstrated it can be salvaged is usually a good candidate for future salvage as well.
- Retain all information of building materials and archive for reference throughout life of the building and at end of life.

---

<sup>3</sup> Cradle to Cradle Certification: “Products are assessed for environmental and social performance across five critical sustainability categories: material health, material reuse, renewable energy and carbon management, water stewardship, and social fairness. A product is assigned an achievement level (Basic, Bronze, Silver, Gold, Platinum) for each category.” <https://www.c2ccertified.org/get-certified/product-certification>

***Fasteners and connection points:***

- Use bolted, screwed or nailed (mechanical) connections instead of glues or sealant (chemical) connections
- Simple forms allow for fewer parts needed and therefore, a simpler disassembly
- When using fasteners, use fasteners that require only standard tools to allow for simple and fast disassembly
- Make fastening points easy to access
- Retain all information on connection points and archive for reference throughout life of the building and at end of life.

***Assembly design:***

- Considering the layering of materials in building components to align with their anticipated life span<sup>4</sup>
- Design assemblies so that materials are independent of each other as much as possible. This way they are not reliant on other materials to allow for repairs and renovations that minimize waste in the future
  - Separate the cladding from the structure
- Separate MEP system from walls and other materials to make them easy to upgrade and change in the future.
- Retain all information on assembly design and archive for reference throughout life of the building and at end of life.

## RECOMMENDED CONSTRUCTION TECHNIQUES FOR WOOD

Mass timber construction can potentially be an advantageous construction technique in design for disassembly for residential construction as well as other building types for many reasons:

- Low weight-to-strength ratio for ease of handling at end of life
- Easier to design for connection points that are more easily disassembled than other construction techniques
- Reuse potential at its end of life

*Photos: Josh Partee Photography*

Source: <https://www.awc.org/pdf/education/des/ReThinkMag-DES315A1-ConnectionOptionsForWoodFrameBuildings-1604.pdf>

Mass timber techniques includes:

- Cross Laminated Timber (CLT)
- Nail Laminated Timber (NLT)
- Glulam Timber

When designing mass timber connection points, consider the following:

- Use connection points that use bolts instead of rivets
- Avoid using gang nail plates that are time consuming to disassemble.
- Avoid using dowels if possible. If dowels are required, avoid using bonding agents like glues.

The more fixed the building component connections, the more difficult the salvage of this material. The more flexible a connection point is, the more interchangeable its components are that make it easier to fix, replace, remove, recycle and/or reuse. The following table gives examples of connection types based on the protocol developed by Buildings as Material Banks<sup>5</sup>.

#### Connection Types

Fixed	Glue/chemical connections	No reuse/recycling
↑	Fixing device, fasteners	↑
↓	Dowel joints, rivet connections	↓
Flexible	Metal hangers	All elements reused/recycled

## CLOSING THE LOOP WITH SALVAGED MATERIALS

Integrating salvaged materials into new construction is an important step in creating a circular economy within the construction industry.

### 1 Building Material Life Cycle

Using salvaged materials in the design and construction of a new building adds depth to the building. It provides a narrative to the project. Especially if the salvaged materials are sourced from the community or from the existing site, it connects the new building to its surroundings and to the past.

There are some fundamental changes to the design and construction process that are needed to be able to effectively use salvage in new construction:

- Salvaged materials need to first be inventoried and assessed, sizes and availability determined, and the building design based on these sizes and quantities. You are unlikely to be able to source significant quantities of salvaged materials suitable for a pre-existing design, with the exception of “standard” sized building materials such as bricks.
- Given the need to source some salvaged materials prior to design, storage of the materials from pre-design to construction needs to be arranged. Improperly stored materials are susceptible to water and weather damage.
- Utility is not equivalent to functionality. Building elements that can no longer function in their original application (exterior glazing for example) may still have utility in another (interior sidelites).
- Readily available non-building waste materials can be considered for construction if they are able to meet the performance characteristics required for the application in which they would be installed. Everything from bottles and tires to shipping containers have been utilized in this way.

Structural elements have the highest potential for reuse with the most value. The following are basic recommendations for using salvaged timber in new buildings<sup>6</sup>:

1. Divide the spatial programme into smaller rooms or volumes
2. Split the structure into smaller sections
3. Avoid equal spans and dimensions
4. Split the structure according to the function
5. Utilize efficient forms that allow using smaller pieces for longer spans
6. Define ranges instead of fixed properties
7. Rotate and repurpose
8. Select the application according to the properties
9. Combine creatively
10. Let the patina speak

Additional resources for using salvaged lumber in new construction:

- [Re-use of structural elements: Environmentally efficient recovery of building components](#)
- [Wood-Framed Building Deconstruction: A Source of Lumber for Construction?](#)

Mass timber is starting to be used on more diverse building types such as high rise (Brock Commons, University of British Columbia) and commercial applications (Mountain Equipment Coop stores) though it is mostly used in residential applications<sup>7</sup>. Countries in the European Union are leading with Design for Disassembly in the construction industry and there is opportunity kickstart the local circular economy.

## CONCLUSION

It is critical when implementing DfD strategies within a project to have buy-in from the team. Being clear about any additional cost implications or cost savings is important in communicating with the owner group. It is also crucial to have a design team that are engaged in DfD principles to spearhead the effort and lead the team. A structural engineer who is interested in working on integrating salvaged structural lumber or other types of elements into a building is important in closing the loop. In order to ensure these techniques are carried through from design to construction, include as many of these strategies in the project specifications so that there is leverage to realize a truly circular project.
